Reverse Engineering of Generative Models: Inferring Model Hyperparameters from Generated Images – Supplementary material –

Vishal Asnani, Xi Yin, Tal Hassner, Xiaoming Liu

1 TEST SETS FOR EVALUATION

The experiments described in the text were performed on four different test sets, each set containing twelve different GMs for the leave out testing. For test sets, we follow the distribution of GMs as follows: six GANs, two VAEs, two ARs, one NF and one AA model. We select this distribution because of the number of GMs of each type in our dataset which has 81 GANs, 13 VAEs, 11 ARs, 5 NFs and 6 AAs. The sets considered are shown in Table 1.

2 GROUND TRUTH FOR GMs

We collected a fake face dataset of 116 GMs, each of them with 1,000 generated images. We also collect the ground truth hyperparameters for network architecture and loss function types. Table 2 shows the ground truth representation of the network architecture where different hyperparameters are of different data types. Therefore, we apply min-max normalization for the continuous type parameters to make all values in the range of [0, 1]. For multi-class and binary labels, we further show the feature value for different labels in Table 3. Note that some parameters share the same values but with different meanings. For example, F14 and F15 represent skip connection and down-sampling respectively. Table 4 shows the ground truth representation of the loss function types used to train each GM where all these values are binary indicating whether the particular loss type was used or not.

3 NETWORK ARCHITECTURE

Figure 5 shows the network architecture used in different experiments. For GM parsing, our FEN has two stem convolution layers and 15 convolution blocks with each block having convolution, batch normalization and ReLU activation to estimate the fingerprint. The encoder in the PN has five convolution blocks with each block having convolution, pooling and ReLU activation. This is followed by two fully connected layers to output a 512 dimension feature vector which is further given as input to multiple branches to output different predictions. For continuous type parameters, we use two fully connected layers to output a 9-D network architecture. For discrete type parameters and loss function parameters, we use separate classifiers with three fully connected layers for every parameter to perform multi-class or binary classification. For the deepfake detection task, we change the architecture of our FEN network as current deepfake manipulation detection requires much deeper networks. Thus, our FEN architecture has two stem convolution layers and 29 convolution blocks to estimate the fingerprint. For further classification, we use a shallow network of five convolution blocks followed by two fully connected layers.

For the image attribution task, we use the same FEN as used in model parsing, and a shallow network of two convolution blocks and two fully connected layers to perform multi-class classification.

4 FEATURE HEATMAPS

Every hyperparameter defined for network architecture and loss function type prediction may depend on certain region of the input image. To find out which region of the input image our model is looking at to predict each hyperparameter, we mask out 5×5 region from the input image. For the continuous type parameters, we compute the L_1 error between every predicted hyperparameter and its ground truth. This value of error will tell us how important is this 5 region in the input image to predict a particular hyperparameter. The higher the value of this error, the higher is the importance of that region in the prediction of the corresponding hyperparameter. For discete type parameters in network architecture and loss function, we estimate the probability of the ground truth label for every parameter. We subtract this probability from one to estimate the heatmap of the respective feature. Important regions will not affect the probability of the ground truth label for a particular feature. To obtain a stable heatmap, we do the above experiment on 100 randomly chosen images across the different GMs and then calculate the average heatmap.

Figure 1, 2 and 3 show the feature heatmaps for every hyperparameter of network architecture and loss type feature vector for Face, MNIST and CIFAR data respectively. For each hyperparmater, there are certain regions of the input that are more important than others. Each type of data has different type of heatmaps indicating different regions of importance. For face and CIFAR, these regions lie mostly in the central part but for MNIST, many of the features depend on the regions closer to edges. There are also some similarities between these heatmaps

TABLE 1: Test sets used for evaluation. Each set contains six GANs, two VAEs, two ARs, one AA and one NF.

| GM | Set 1 | Set 2 | Set 3 | Set 4 | | | | | | | | |
|-------------|-------------|------------|---------------------|---------------------|--|--|--|--|--|--|--|--|
| GM 1 | ADV_FACES | AAE | BICYCLE_GAN | GFLM | | | | | | | | |
| GM 2 | BETA_B | ADAGAN_C | BIGGAN_512 | IMAGE_GPT | | | | | | | | |
| GM 3 | BETA_TCVAE | BEGAN | CRGAN_C | LSGAN | | | | | | | | |
| GM 4 | BIGGAN_128 | BETA_H | FACTOR_VAE | MADE | | | | | | | | |
| GM 5 | DAGAN_C | BIGGAN_256 | FGSM | PIX2PIX | | | | | | | | |
| GM 6 | DRGAN | COCOGAN | ICRGAN_C | PROG_GAN | | | | | | | | |
| GM 7 | FGAN | CRAMERGAN | LOGAN | RSGAN_REG | | | | | | | | |
| GM 8 | PIXEL_CNN | DEEPFOOL | MUNIT | SEAN | | | | | | | | |
| GM 9 | PIXEL_CNN++ | DRIT | PIXEL_SNAIL | STYLE_GAN | | | | | | | | |
| GM 10 | RSGAN_HALF | FAST_PIXEL | STARGAN_2 | SURVAE_FLOW_NONPOOL | | | | | | | | |

ASNANI ET AL. REVERSE ENGINEERING OF GENERATIVE MODELS

Fig. 1: Feature heatmap for each feature in network architecture and loss function predicted feature vector for face data. Each heatmap provides the importance of the region in the estimation of the respective parameter.

| Feature | Label | Value |
|----------------------------------|-------|---------------------------------|
| | 0 | Batch Normalization |
| Normalization tama | 1 | Instance Normalization |
| Normalization type | 2 | Adaptive Instance Normalization |
| | 3 | No Normalization |
| | 0 | ReLU |
| Non linearity type in last layer | 1 | Tanh |
| Non-meanty type in fast fayer | 2 | Leaky_ReLU |
| | 3 | Sigmoid |
| | 0 | ELU |
| Non linearity type in blocks | 1 | ReLU |
| Non-intearity type in blocks | 2 | Leaky_ReLU |
| | 3 | Sigmoid |
| I Incompling town | 0 | Nearest Neighbour |
| Opsampling type | 1 | Deconvolution |
| Skin connection and downcompling | 0 | Feature used |
| Skip connection and downsampring | 1 | Feature not used |

TABLE 3: Feature value for different labels of multi-class and binary features.

(b) Weighted cross entropy

Fig. 4: Confusion matrix in the estimation of remaining parameters which were not shown in paper for network architecture and loss function. (1)-(12): Standard cross-entropy and (12)-(24): Weighted cross entropy. Weighted cross entropy handles imbalance of data much better than the standard cross entropy which usually predicts one class.

Fig. 5: Network architecture for various components of our method. (a) FEN (b) Mean and instance parser in PN (c) Shallow network for deepfake detection (d) Shallow network for image attribution.
